FFT.cpp

Description: fft(a) computes $\hat{f}(k) = \sum_x a[x] \exp(2\pi i \cdot kx/N)$ for all k. N must be a power of 2. Useful for convolution: conv(a, b) = c, where $c[x] = \sum a[i]b[x-i]$. For convolution of complex numbers or more than two vectors: FFT, multiply pointwise, divide by n, reverse(start+1, end), FFT back. Rounding is safe if $(\sum a_i^2 + \sum b_i^2) \log_2 N < 9 \cdot 10^{14}$ (in practice 10^{16}; higher for random inputs). Otherwise, use NTT/FFTMod.
Time: $\mathcal{O}(N \log N)$ with $N = |A| + |B|$ ($\sim 1s$ for $N = 2^{22}$)   f04f0c, 34 lines

HopcroftKarp.cpp

Description: Fast bipartite matching algorithm. Graph *g* should be a list of neighbors of the left partition, and *btoa* should be a vector full of -1's of the same size as the right partition. Returns the size of the matching. *btoa*[i] will be the match for vertex *i* on the right side, or -1 if it's not matched.

Usage: vi btoa(m, -1); hopcroftKarp(g, btoa);

Time: $\mathcal{O}\left(\sqrt{V}E\right)$

2ff797, 42 lines

```cpp
bool dfs(int a, int L, vector<vi>& g, vi& btoa, vi& A, vi& B

```

MinCostMaxFlow.cpp
Description: Min-cost max-flow. cap[i][j] != cap[j][i] is allowed; double edges are not. If costs can be negative, call setpi before maxflow, but note that negative cost cycles are not supported. To obtain the actual flow, look at positive values only.
Time: Approximately $\mathcal{O}\left(E^2\right)$

```cpp
const ll INF = numeric_limits<ll>::max() / 4;
typedef vector<ll> VL;

using pii = pair<int, int>;
struct MCMF {
  int N;
  vector<vi> ed, red;
  vector<VL> cap, flow, cost;

    }
    return combine(resL,resR);
}
```

SideOf.cpp

Description: Returns where p is as seen from s towards e. 1/0/-1 ⇔ left/on line/right. If the optional argument eps is given 0 is returned if p is within distance eps from the line. P is supposed to be Point<T> where T is e.g. double or long long. It uses products in intermediate steps so watch out for overflow if using int or long long.
Usage: bool left = sideOf(p1,p2,q)==1;

3af81c, 9 lines

```
template<class P>
int sideOf(P s, P e, P p) { return sgn(s.cross(e, p)); }

template<class P>
int sideOf(const P& s, const P& e, const P& p, double eps) {
    auto a = (e-s).cross(p-s);
    double l = (e-s).dist()*eps;
    return (a > l) - (a < -l);
}
```

Simplex.cpp

Description: Solves a general linear maximization problem: maximize $c^T x$ subject to $Ax \le b$, $x \ge 0$. Returns -inf if there is no solution, inf if there are arbitrarily good solutions, or the maximum value of $c^T x$ otherwise. The input vector is set to an optimal x (or in the unbounded case, an arbitrary solution fulfilling the constraints). Numerical stability is not guaranteed. For better performance, define variables such that $x = 0$ is viable.
Usage: vvd A = {{1,-1}, {-1,1}, {-1,-2}};
vd b = {1,1,-4}, c = {-1,-1}, x;
T val = LPSolver(A, b, c).solve(x);
Time: $\mathcal{O}(NM \cdot \#pivots)$, where a pivot may be e.g. an edge relaxation. $\mathcal{O}\left(2^N\right)$ in the general case.

SphericalDistance.cpp

Description: Returns the shortest distance on the sphere with radius radius between the points with azimuthal angles (longitude) f1 (ϕ_1) and f2 (ϕ_2) from x axis and zenith angles (latitude) t1 (θ_1) and t2 (θ_2) from z axis (0 = north pole). All angles measured in radians. The algorithm starts by converting the spherical coordinates to cartesian coordinates so if that is what you have you can use only the two last rows. dx*radius is then the difference between the two points in the x direction and d*radius is the total distance between the points.

611f07, 8 lines

```
double sphericalDistance(double f1, double t1,
        double f2, double t2, double radius) {

SuffixTree.cpp

Description: Ukkonen's algorithm for online suffix tree construction. Each node contains indices [l, r) into the string, and a list of child nodes. Suffixes are given by traversals of this tree, joining [l, r) substrings. The root is 0 (has l = -1, r = 0), non-existent children are -1. To get a complete tree, append a dummy symbol – otherwise it may contain an incomplete path (still useful for substring matching, though).
Time: $\mathcal{O}(26N)$
07bb84, 50 lines

Math Hints (2)

Newton's Method: $x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$.

Lagrange Multiplier: Let $f : \mathbb{R}^n \to \mathbb{R}$ be the objective function, $g : \mathbb{R}^n \to \mathbb{R}^c$ be the constraints function, let x^* be an optimal solution to the optimization problem such that $Dg(x^*) = c$: maximize $f(x)$ subject to $g(x) = 0$. There there exists λ such that $Df(x^*) = \lambda^* \top Dg(x^*)$.

Burnside's Lemma: Let G be a finite group acting on set X. Let X^g denote the set of elements in X that are fixed by g. Then the number of orbits is given by $|X/G| = \frac{1}{|G|} \sum_{g \in G} |X^g|$.

Linear Time Inverses Modulo p: For $i \geq 2$, $i^{-1} = -\lfloor \frac{p}{i} \rfloor (p \bmod i)^{-1}$.

Quadratic Residue: $\left(\frac{a}{p}\right) = a^{(p-1)/2}$. If $x^2 \equiv a (\bmod p)$ has a solution, then $\left(\frac{a}{p}\right) = 1$.

LGV Lemma: Assume $G = (V, E)$ is a DAG. Let $\omega(P)$ be the product of edge weights on path P. Let $e(u, v) := \sum_{P:u \to v} \omega(P)$ be the sum of $\omega(P)$ for all paths from u to v. The set of sources $A \subseteq V$ and set of sinks $B \subseteq V$. A collection of disjoint paths $A \to B$ consists of n paths S_i such that S_i is a path from A_i to $B_{\sigma(S)_i}$ such that for any $i \neq j$, S_i and S_j does not share a common vertex. Then if we let

$$M = \begin{bmatrix} e(A_1, B_1) & e(A_1, B_2) & \cdots e(A_1, B_n) \\ \vdots & \vdots & \ddots & \vdots \\ e(A_n, B_1) & e(A_n, B_2) & \cdots & e(A_n, B_n) \end{bmatrix},$$

then $\det M = \sum_{S:A \to B} \text{sgn } \sigma(S) \prod_{i=1}^n \omega(S_i)$ where $S : A \to B$ denotes a set of disjoint paths S from A to B.

Network Flow with Lower/Upper Bounds: Suppose the flow must satisfy $b(u, v) \leq f(u, v) \leq c(u, v)$, and have conservation of flows over vertices.

Variant 1: No source/sink (i.e. flow at all vertices must be balanced), check if there is a feasible flow: create a graph G'. For any edge $u \to v$, add an edge with capacity $c(u, v) - b(u, v)$. Now assume initially, at vertex u, the sum of capacities of edges into u minus the sum of capacities out of u is M. If $M > 0$, add an edge from super source S to u with capacity M. If $M < 0$, add an edge from u to the super sink T with capacity $-M$.

Variant 2: Feasible flow with sources and sinks: Add an edge from original sink t to source s with capacity $+\infty$.

Variant 3: Maximum flow with sources and sinks: first, check if there exists a feasible flow. Then augment using source s and sink t (i.e. run Dinic again with source s and sink t).

Variant 4: Minimum flow with sources and sinks: find the feasible flow first, remove the edge from sink to source (the current flow on the edge is the size of the original flow), and then run the maximum flow from the sink t to the source s to see how much we may get rid off from the original flow.

Pick's Theorem: Suppose a polygon has integer coordinates for all of its vertices; let i be the number of integer points that are interior to the polyon, b be the number of integer points on its boundary, the area of the polygon is $A = i + \frac{b}{2} - 1$.

Mobius Transformation/Circle Inversion: Mobius transformations $f : \hat{\mathbb{C}} \to \hat{\mathbb{C}}$ are specified by $f(z) = \frac{az+b}{cz+d}$.

Dilworth's Theorem: For a partially ordered set S, the maximum size of an antichain is equal to the minimum number of chains (i.e. any two elements are comparable) required to cover S.

LP Duality: Suppose the primal linear program is given by maximize $\mathbf{c}^\top \mathbf{x}$ subject to $A\mathbf{x} \le \mathbf{b}, \mathbf{x} \ge 0$, the dual progarm is given by minimize $\mathbf{b}^\top \mathbf{y}$ subject to $A^\top \mathbf{y} \ge \mathbf{c}, \mathbf{y} \ge 0$.

Mobius Inversion: If g, f are arithmetic functions satisfying $g(n) = \sum_{d|n} f(d)$ for $n \ge 1$, then $f(n) = \sum_{d|n} \mu(d) g(\frac{n}{d})$.

Number of Points on Lattice Convex Polygon: A convex lattice polygon with coordinates in $[0, N]$ has at most $O(N^{2/3})$ points.

Green's Theorem: Let C be a positively oriented, smooth, simple closed curve and let D be the region bounded by C. If L and M are functions of (x, y) defined on an open region containing D and having continuous partial derivatives, then
$$\int_C (L dx + M dy) = \int_D (\frac{\partial M}{\partial x} - \frac{\partial L}{\partial y}) dx dy.$$

Polynomial Division: Suppose we are given polynomials $f(x), g(x)$, and we want to write $f(x)$ as $f(x) = Q(x)g(x) + R(x)$. Let $f^R(x) = x^{\deg f} f(\frac{1}{x})$ (i.e. reverse the coefficients of the polynomial). Let $n = \deg f, m = \deg g$. Then
$$f^R(x) \equiv Q^R(x)g^R(x) \mod x^{n-m+1}/$$
